Abstract

Hypersensitivity Pneumonitis (HP) is an immune-mediated syndrome triggered by inhalation of a wide variety of allergens, to which individual is previously sensitized. More than 200 responsible agents for the disease have already been identified; however, HP occurs only in a small number of individuals exposed to causal antigens. Thus, the present report provides an overview of antigen's role in HP, highlighting its diversity, research methods and prevention strategies, as also antigen's eviction impact on disease prognosis.

HP is an underdiagnosed disease, and therefore, it is difficult to accurately estimate its incidence. Triggering antigens can be divided into 6 broad categories: bacteria, fungi, mycobacteria, animal and plant proteins, chemicals and metals, represented by disease prototypes. The identification of causal antigen is a major challenge, being unable to be obtained in about 30-60% of cases. The acute form of HP, with early detection and immediate eviction of causal antigen, tends to have an excellent prognosis. In the chronic form, still remains possible a partial recovery of disease; however, some cases tend to progress to fibrosis, even after exposure removal.

In conclusion, HP diagnosis should be based on a proactive search for potential antigen sources, although their identification is hampered by the lack of standardized methods to demonstrate the specific antigen sensitization. Antigen avoidance is a critical determinant on disease prognosis.

KEYWORDS: Hypersensitivity Pneumonitis, Antigen, Research Methods, Diagnosis, Prognosis.

Introduction

Hypersensitivity pneumonitis (HP), also known as extrinsic allergic alveolitis, is an immune-mediated syndrome that results from lung parenchyma and small-caliber respiratory tract inflammation. This reaction is secondary to a repeated and prolonged specific antigens inhalation to which individual is sensitized.¹ There are more than 200 antigens already identified as causal agents of HP, that can be found in workplace, at home, and in recreational activities. The huge majority are derived from fungi, bacteria, protozoa and animal proteins, or even low molecular weight chemical compounds.² Further, clinical presentation and disease progression can be extremely variable, depending from the nature of causal agent, exposure duration, and intensity, as well as individual host factors.^{1,3,4}

The incidence and prevalence of HP are difficult to estimate accurately, mostly due to it under-diagnosis, which may be partly explained by absence of widely accepted diagnostic criteria.^{3,4} Additionally, HP prevalence varies from country to country (and even within the same country), according to geographical conditions, local practices (agricultural and industrial) and host risk factors.^{3,5} For example, epidemiologic data show an incidence of HP in Europe ranging from 0.3 up to 0.9 per 100.000 inhabitants.⁶⁻⁸ In fact, the annual incidence in Denmark is less than 1 per 100 000 inhabitants,⁷ while in New Mexico is about 30 per 100 000 inhabitants,⁹ and a prospective study carried out in India revealed that HP is the most common interstitial lung disease (47.3% of cases).¹⁰

Several HP diagnostic criteria have been proposed, but none of them has yet been validated so far. As such, diagnosis is based on integration of clinical, radiological and pathological data.¹¹ Identification of causal antigen is crucial, not only for diagnosis but also prevention and even prognosis of disease. However, this issue represents a major challenge, mostly due to the lack of standardized techniques.⁵

In this sense, this report aims to provide an overview of antigen's role in HP, highlighting its diversity, research methods and prevention strategies, as also antigen's eviction impact on disease prognosis.

From antigen to disease

The first descriptions of a pulmonary disease similar to HP, as it is known today, appeared in 1713, associated with people who worked with cereals.¹² However, it was only in 1932 that Campbell firstly described Farmer's lung (FL), the disease that became the classic example of HP.¹³ In 1959, the respiratory disease was described in mushroom workers, caused by inhalation of compounds contaminated by thermophilic actinomycetes.¹⁴ In 1960, the disease was described in workers who contact with birds, initially associated with ducks and turkeys, and later also with parakeets and pigeons (Bird-breeder's lungs).¹⁵ From this date onwards, other agents were progressively reported as having a direct contribution to the onset of this disease, being currently identified more than 200 causal antigens.^{2,3} HP only develops in a small proportion of individuals exposed to causal antigens; in fact, when exposed to the same causal agent, most individuals are only sensitized, leading to a small increase of lymphocytes locally, but without clinical relevance, which suggests the existence of host's intrinsic factors in its pathogenesis.^{4,5,16,17} **(Figure 1)**

The coexistence of triggering (e.g., antigen exposure) and promoting factors, such as Major Histocompatibility Complex (MHC II) gene polymorphisms, low molecular weight proteasomes, transporters associated with antigen processing-1 (TAP1) or other exposures, such as viruses, may lead to the development of an exacerbated immune reaction resulting in persistent lung inflammation.^{3,17} In fact, the inhalation of causal antigen leads to an inflammatory reaction, with the release of cytokines and pro-

inflammatory mediators, among others, type 1 T helper (Th1), tumor necrosis factor- α (TNF α), interleukin 12 (IL-12) and interferon gamma (INF- γ).¹⁸ Thereafter, the continued exposure, local antibody production and/or presence of genetic susceptibility lead to critical changes in the lung, namely fibroblast expansion and activation, and extracellular matrix deposition.¹⁷ (**Figure 1**)

An interesting aspect to highlight is that HP is less frequent in cigarette smokers. In fact, nicotine is thought to inhibit macrophage activation, and lymphocyte proliferation and function, but this does not apply to ex-smokers.¹⁹ On the other hand, in smokers who develop HP, fibrosing disease with a worse prognosis is more common.²⁰

Concerning to clinical behavior, HP can be traditionally divided into three distinct phenotypes: acute, subacute and chronic (**Table 1**). There is a considerable controversy surrounds this classification, because no widely accepted criteria exist to distinguish the various stages. In fact, the subacute form is considered by some authors as a variant of acute HP.^{1,4} Lacasse et al. (2009) performed a cluster analysis suggesting that HP patients should be classified into only 1 of 2 categories, based on clinical evaluation, pulmonary function tests, and high-resolution computed tomography findings.²¹ As such, some authors have proposed an alternative classification that includes acute or episodic HP, chronic HP with acute episodes, and chronic HP without acute episodes.²² More recently, Vasakova et al. (2017) proposed a novel HP classification into two main categories: acute/inflammatory HP and chronic/fibrotic HP, based on clinical-radiologic-pathologic correlation, with a considerable prognostic value.⁶

Antigenic diversity

As already mentioned, HP may be induced by a wide and growing variety of antigens, that can be divided into 6 broad categories: bacteria, fungi, mycobacteria, animal and plant proteins, chemicals and metals, represented by disease prototypes.³ (**Table 2**)

The list of HP-associated environments is increasing, but in most situations, the disease is caused by similar antigens in distinct environments.¹⁸ Recently, Millon et al. (2016) have shown the existence of common antigenic amino acid sequences in orthologous proteins from a fungus belonging to *Mucorales* order and a *Mycobacterium* species, each one acting as a main etiologic agent of a specific HP form.²³ The existence of common epitopes in orthologous immunogenic proteins from microorganisms belonging to greatly different phylogenetic families explains how, in some cases of HP, a growing number of etiologic agents have been found in the same disease.²³ HP can effectively arise in any environment, including workplace, housing, and recreational activities, where bacteria and fungi grow or birds are kept.²⁴ Further, drugs can also cause HP, constituting a non-inhaling variant of the disease. In fact, the number of HP-associated drugs is increasing, with more than 380 drugs already reported;²⁵⁻²⁸ therefore, it is extremely relevant to exclude this cause, frequently missed. The individuals with higher risk of developing HP are those working in agriculture, poultry and livestock industries; workers using fluid metals;²⁹⁻³¹ cheese, sausages or flour processing;³²⁻³⁴ malt or soy sauce manufacturers.³⁵ The risk also increases during wood processing (e.g. cork oak bark) and construction; textiles, clothing or plastics manufacturing; and even in individuals who work with paints, paint hardeners or other chemical products.^{36,37} However, in about 30-60% of cases, antigen remains hidden or unrecognized, even existing some authors who suggested the use of “cryptogenic HP” for such patients.^{6,38}

Types of disease according to antigen class

Bacterial exposure

Farmer's lung (FL) is considered the HP prototype. Although it is still under-diagnosed, this is one of the most prevalent types of disease, and in which bacteria are the most common responsible antigens. This form of the disease is triggered by inhalation of antigens from housed microorganisms, at high humidity conditions, in hay, straw and grain dust stored in agricultural yards.²⁹ FL responsible antigens vary from country to country and depend on climate, farming and production conditions.³⁹ Thermophilic actinomycetes, such as *Saccharopolyspora rectivirgula*, *Thermoactinomyces vulgaris*, *Thermoactinomyces viridis* and *Thermoactinomyces sacchari*, are the most frequently described agents.^{29,40} However, in some cases, FL disease results from fungal exposure, such as *Alternaria*, *Aspergillus fumigatus* and *Botrytis* species.⁴¹ Further, Reboux et al. (2006) identified *Absidia corymbifera*, *Eurotium amstelodami* and *Wallemia sebi* as main causal agents to FL in France.⁴² In fact, all these organisms typically reproduce at high humidity zones and temperatures of 40-60 °C; therefore, this form of HP is more frequent in regions where agriculture predominates, especially in rainy and hot seasons.⁴² Despite the disease prevalence in exposed farmers is not well-known, several studies have reported similar findings, placing the prevalence in 0.5 to 4.4 %.^{43,44}

Fungal exposure

Molds have been described for years as a common cause of occupational HP.⁴⁵ In fact, a mold is a type of fungus that grows in damp areas; it releases tiny particles, commonly called as spores, that can be harmful when breathed in.⁴⁶ Mold-induced HP has been increasingly reported as being caused by humidifiers, heating and ventilation systems contaminated by *Aspergillus*, *Cladosporium*, *Penicillium*, *Aureobasidium pullulans*,

Cephalosporium or *Mucor* species.⁴⁵ (**Table 2**) However, molds can be found in other unexpected home reservoirs, such as fruits and vegetables, leading to various forms of HP, such as onion worker's lung, potato worker's lung or fruit grower's lung;⁶ moldy tapestry with *Penicillium*, *Cladosporium* or *Botrytis* species;⁴⁶ and even flower pots, whose inhalation of mold spores containing *Pullularia pullulans*, *Trichoderma viride*, *Cephalosporium acremonium* or *Aspergillus fumigatus* may lead to HP.⁴⁷ All these exposure sources can go completely unnoticed in a domestic environment, and possibly more frequent than widely recognized. So, a thorough visit of the whole house is advisable in search of mold stains, even of unnoticed size, humidity, condensation or musty odor.^{45,48}

Summer-type HP (SHP) is the most common form of domestic HP in Japan, especially in the western and southern parts of the country, being also some cases reported in other Asian countries.⁴⁹ SHP is caused by repeated inhalation of fungi *Trichosporon* species, namely *Trichosporon cutaneum*, which contaminates domestic environments, usually wooden houses, during hot and humid summers, and after a rainy season.^{49,50} *Trichosporon cutaneum* develops at temperatures between 25-28 °C and a relative humidity above 80%, especially in the presence of wet wood or vegetation.⁵⁰ An epidemiological study on HP performed in Japan in the 1980s showed that the proportion of SHP cases in patients with HP was 74.4%.⁵¹ However, more recently, Iijima et al. (2017) verified that the incidence seems to be decreasing, mainly due to changes in residential environments, although climatic conditions in any year may cause a temporary increase in the incidence rate.⁵²

Suberosis, also known as corkhandler's disease or corkworker's lung, is another form of HP caused by fungi existing in the working environment; it occurs in cork workers and has been mainly reported in Portugal.⁵³⁻⁵⁷ Cork oak is the second most dominant forest

species in Portugal, making this country the world's leading exporter of cork, followed by Spain.^{58,59} The processes used in cork manufacture depend on the end product to be obtained; however, during this process, workers are exposed to a heavily contaminated environment with moldy cork dust.⁵⁵ The most frequent cork colonizing fungi during its industrial processing are *Penicillium glabrum* (formerly known as *Penicillium frequentans*) and *Chrysosporium sitophilum*. *Penicillium glabrum* is the main causative agent of suberosis, but during the storage period, cork can also be colonized by other fungi, such as *Aspergillus fumigatus* or *Mucor* species.^{55,56} In Portugal, it has been estimated that 9 to 19% of cork workers may develop suberosis.^{53,54}

In recent decades, several other different forms of disease caused by fungi have been described in the literature. HP can also be observed in individuals working with woods colonized by fungi, namely *Aspergillus* and *Penicillium* species, *Cryptosporium corticale*, *Alternaria* species, among others. The first cases were reported when conventional outdoor drying of wood was replaced by indoor drying in special ovens, as well as in the indoors wood sorting and cutting, in order to improve working conditions in sawmills.³⁶ Some cases have been reported in food industry workers, such as bakers who are exposed to flour on a daily basis, that can be contaminated with the fungi *Aspergillus fumigatus*;³³ cheese producers can also develop cheese workers' HP caused by *Penicillium notatum*, *Penicillium viridicatum*, *Aspergillus fumigatus*, *Aspergillus niger* or *Aureobasidium pullulans*;³⁴ in soy sauce brewer, where precipitin against *Aspergillus oryzae* was found (soya dust alveolitis);^{6,35} and even in salami factory workers due to inhalation of dried sausage dust. Morell et al. (2011), for example, described five Spanish patients working in dry sausage production with Salami Brusher's disease, caused by *Penicillium glabrum* and *Aspergillus fumigatus*.³²

In conclusion, fungal exposure can have various sources, variable in frequency but highly troublesome; so, an increasing awareness on their detection should be taken, both in any patient daily activities, as for instance musicians, mainly saxophonists that may inhale fungi *Candida albicans*, *Phoma* species or *Ulocladium botrytis*, presents in the instrument mouthpiece (Sax Lung disease).⁶⁰

Animal proteins exposure

Bird fancier's lung (BFL), or bird breeder's disease, is a complex syndrome caused by the repeated inhalation of avian proteins through the form of bird droppings, feathers or secretions, triggering an exaggerated immune response to the antigen and consequent HP in sensitized individuals.⁶¹ Less often, the inhalation may occur from feathers of duvets or pillows.⁶² BFL is most frequently reported after exposure to pigeons and birds belonging to the *Psittaciformes* order, including cockatoos, parakeets, and parrots. Else, some cases of BFL resulting from poultry exposure, including chickens, turkeys, geese, and ducks have also been reported.^{30,63} (**Table 3**)

The prevalence of this form of disease varies geographically, might be partially explained by the local climate, availability of medical resources, local cultural habits, racial factors, smoking habits and even exposure duration and intensity. However, it is known that BFL is the most common form of HP worldwide, corresponding to 66-68% of all HP forms,³⁰ with a prevalence ranging from 6-20% in exposed pigeon breeders.⁶¹ In Portugal, some studies have reported a prevalence of BFL ranging from 2 to 5%.^{64,65} On the other hand, the acute, subacute and chronic presentations of BFL have also been recognized, but often overlap clinically to each other. Anyway, a continuous antigen exposure in chronic phase presents a worse prognosis.³⁰

Mycobacterial exposure

Hot tub baths have become increasingly common in homes, as well as in hotels and spas. Recently, these baths have been associated with an emerging disorder, known as Hot Tub Lung (HTL).⁶⁶

HTL is a lung disease that can be caused by inhalation of hot water aerosols from hydromassage baths (the majority of cases found in literature), but can also occur in public recreational water facilities, such as swimming pools, saunas and spas, since these waters are contaminated by nontuberculous mycobacteria (NTM), in most cases belonging to the *Mycobacterium avium complex* (MAC).^{66,67}

MAC mainly consists of two mycobacteria species, namely *Mycobacterium avium* and *Mycobacterium intracellulare*.⁶⁸ It is the hydrophobic nature of *Mycobacterium avium* and *Mycobacterium intracellulare* and the high content of mycolic acid present in their cell walls that makes MAC highly resistant to disinfectants commonly used in swimming pools and spas. They withstand temperatures up to 42°C, exceeding the higher limit of temperature established in spas.⁶⁷ Glazer et al. (2007) reported that *Mycobacterium avium* and other NTMs were found in 72% of the air and water samples randomly collected from 18 swimming pools; concentrations were significantly lower in chlorine and bromide disinfected pools than in those disinfected with hydrogen peroxide and ultraviolet light.⁶⁹ A relatively recent example of HP induced by mycobacteria is metal workers exposed to aerosolized metalworking fluids (MWF) contaminated with NTM, namely *Mycobacterium chelonae* and *Mycobacterium immunogenum*. MWF are complex mixtures of oil and water commonly used as refrigerants and lubricants in various industries.³¹

Chemical Exposure

Chemically-induced HP is an uncommon entity; however, several substances capable of causing the disease have already been described.⁶ (**Table 2**) Acrylate compounds, such as methyl methacrylate are associated with an increased incidence of HP in dentists. This increase seems to be associated with the substitution of amalgam fillers by acrylate fillers in dental care.⁷⁰ On the other hand, isocyanates are highly reactive reagents, widely used on polyurethane polymers production for flexible and rigid foams, such as elastomers, adhesives, surface coatings and paints.⁷¹ Several cases of HP caused by these reagents have already been reported, mainly related to spray painting or plastics manufacture.³⁷ Other compounds, such as anhydrides used in plastics, paints, resins, and glues, as also triglycidyl isocyanurate, often used in paints, are also recognized as causing HP.^{30,72} The prevalence of isocyanate-induced HP, related to the plastic manufacturing process, is 1.3% of all chronic HPs in Japan, having only been reported three cases over a ten's year period.^{71,73}

Methods for antigen determination

The identification of the causal antigen is crucial, not only for the diagnosis but also for establishing preventive measures and of disease prognosis. All available tools to detect the source of exposure should be used.⁵

Clinical history

The first step is to collect a highly detailed clinical history so that it will be possible to uncover or to assume the exposure source, either in domestic, recreational or work setting.

⁵ The use of a standardized questionnaire can be very useful in identifying exposures,

otherwise undetected in a more informal discussion with the patient; however, these questionnaires need validation prior being used in clinical practice.⁶

Specific antibodies

The second step requires the use of laboratory tests to confirm the presence of immunologic sensitization to a suspected antigen, classically using a precipitation reaction between patient's sera and causal antigen extracts for detection of specific antibodies, mainly of the immunoglobulin G (IgG) class.⁵ The presence of specific IgG antibodies reflects an immune response to a specific exposure, indicating that the individual had a sufficient exposure level to the antigen to develop sensitization. However, in itself, this aspect is not sufficient to establish the diagnosis, since many asymptomatic individuals show a similar level of humoral responses.¹⁶ In fact, precipitins are only an exposure marker. Antibodies precipitating against potential antigens may be present in serum and bronchoalveolar lavage (BAL) samples from individuals with HP, but also in some asymptomatic exposed to the same antigens. Up to 40% of farmers exhibit positive serum precipitins in the absence of clinically significant manifestation of the disease, with no long-term squeal,³ as shown by one study evaluating 43 asymptomatic milk producers who had serum antibodies specific for FL antigens and did not develop abnormal lung function tests during a 20-year follow-up period.⁷⁴ Nonetheless, a positive serum antibody testing is a significant predictor of HP (odds ratio: 5.3; 95% confidence interval: 2.7–10.4)⁷⁵ although the absence of serum precipitin does not exclude an HP diagnosis.² Fenoglio et al. (2007) found that serum precipitins were useful for diagnosing acute HP induced by fungi (predictive negative value, 81–88%; predictive positive value, 71–75%).⁷⁶ There are several laboratory methods for qualitative determination of specific antibodies, such as the precipitation reaction of the double

immunodiffusion of Ouchterlony or combined with immunoelectrophoresis; as well as for quantitative determination, namely enzyme-linked immunosorbent assay (ELISA), ImmunoCAP[®] or Immulite[®]. In general, the results obtained using these methods differ considerably,⁷⁷ with ELISA being nowadays the most frequently used.⁷⁸⁻⁸¹ Sandoval et al. (1990), carrying out a comparative study for detection of specific antibodies in BAL of patients with HP, using immunoelectrophoresis and ELISA, found positivity in 12 % and 100 % of cases, respectively, showing its usefulness for antibodies detection against pigeon antigens in fluids with a low protein content.⁸⁰ In another study, Simpson et al. (1992) revealed that the ELISA method showed greater sensitivity (nearly to 10³ times higher) than the double-immunodiffusion method, in patients with BFL.⁸¹ Suhara et al (2015), also reported a high sensitivity and specificity of the antibodies, 80–100% and 92–100%, respectively, in acute bird-related HP, claiming that antibody titers may be lower in chronic bird-related HP, as cellular immunity is more closely associated with chronic bird-related HP pathology than the humoral immunity.⁷⁹

There is a long list of potential antigens in HP, although there is only a limited number of available antigen preparations proposed for detection (**Table 4**). The selection of antigens to be tested should be based on the individual exposure history and in the most prevalent type in each region.^{6,77} In fact, the serum specific IgG (sIgGs) panels used in different centers is determined by practice location. An example of a sIgGs panel include molds, bacteria, animal proteins and chemical substances, as illustrated in **Table 4**.

Currently, clinicians do not have access to tests that allow them to individualize the panel for actual exposure on their patients. In addition, the specific antibodies are not always identified in patients with HP, probably because some of the antigens that cause this condition still remains unknown.⁸² The finding that common peptide epitopes may induce cross-reactivity in HP serodiagnosis can affect this test performance, making the research

for epitopes that are common to different microorganisms, capable of inducing the same antibody response in patients with HP, a current challenge.²³

The lack of reliable standardized techniques and of established physiological intervals for sIgGs levels against possible causal antigens, raise concern about the diagnostic use of this technique.⁵ Thus, it would be advantageous to involve auxiliary specialists, occupational physcists, and industrial or environmental hygienists, in order to obtain more reliable samples for microscopic, microbiological and immunological analysis.⁶ However, and despite all these limitations, this technique is essential to support the HP diagnosis, sometimes determinant to discover new etiologies of the disease, as well as to differential diagnosis between HP and other diseases, such as idiopathic pulmonary fibrosis (IPF).^{74,83}

Specific inhalation challenge

A third method to confirm causality between a suspected antigen and the disease is the specific inhalation challenge (SIC), which presupposes patient exposure to the potentially contaminated environment or through direct inhalation of the antigens or commercially available extracts.⁵ This technique has also been used to confirm a suspected etiologic agent and when there are some doubts concerning the differential diagnosis of chronic HP and IPF.⁸⁴ The focus of SIC is to demonstrate that exposure to a particular agent produces a fall in forced expiratory volume in one second (FEV1), while ensuring that fall remains within safety limits and does not cause serious adverse reactions. Indeed, most authors recommend that, during SIC, exposure should be increased very gradually; in fact, the exposure intensity is of particular relevance to enhance SIC safety, especially with previously unknown sensitizing agents. In this context, it would be very useful to identify patient characteristics that predict a specific response during SIC.⁸⁵ Morell et al.

(2008) proposed that SIC should be considered the “gold standard” among noninvasive BFL diagnostic examinations, focusing on decreased forced vital capacity (FVC) and/or lung diffusing capacity for carbon monoxide (DLCO).⁶³ In fact, this test reveals very satisfactory sensitivities and specificities in experienced centers.⁶ In a study carried out by Muñoz et al. (2014), SIC evidenced a good diagnostic yield in 113 patients with suspected HP. The overall sensitivity and specificity were, respectively, 73 and 84 %, when tests against all causative agents were analyzed together; and 85 and 86 %, respectively, when evaluating results in patients only exposed to avian or fungal antigens.⁸⁶ In the same way, Ishizuka et al. (2015) demonstrated that the sensitivity and specificity for diagnosing chronic BFL were as high as 92.9 % and 94.7%, respectively.⁸⁷ In spite of its “gold standard” status, SIC is rarely performed because it is not standardized nor validated, being required specialized centers with experience in the procedure and with proper equipment for treatment of uncommon, but potential complications.⁷⁷

Prevention

Avoiding exposure to causal agent is the cornerstone of HP management and an important and determinant factor to prognosis, since progression is largely avoidable with adequate antigen eviction.³ Patients should be advised about the relevance of a clean domestic air environment and the absolute necessity of avoiding further exposures to known HP causative agents. However, this eviction is difficult for most patients due to professional or personal issues (e.g. affective links to a pet or fear of abandoning a hobby).⁶ In this sense, an occupational and environmental health professional should carefully recognize individuals at risk, identified through a detailed history and exposure’s evaluation in the workplace, and also collaborate with partners in the local community and employers to raise awareness about the risks of antigen exposure, and even inform them about

preventive measures. Providing simple and accessible educational material can also help to reduce exposure and to facilitate more accurate diagnosis, as well as to incite the use of personal protective equipment, including masks and respirators.⁸⁸

In the specific case of FL exposure, there are three possibilities for reducing repeated inhalation of organic particles and, thus preventing progression to a fibrosing process: 1) definitive withdrawal of patient from workplace, which in most situations is not a feasible solution due to economic issues; 2) improve the storage methods of hay or straw; it has been shown that provision in low-density bundles hinders the growth of microorganisms, rather than round bales with a high concentration of moisture due to the increased hay compaction; 3) use high efficient respiratory protection devices capable of preventing the entry of antigens into the bronchial tree.²⁹ In the case of pigeon breeders, they may be encouraged to spend less time in the loft, and to wear a coat and hat to be removed when exiting the loft, so as to avoid continuous contact with the antigen that can be carried on clothing or hair. Increasing the level of ventilation in the loft can also be useful in reducing antigen exposure.¹⁶ Regarding HTL, World Health Organization recommends that treatment and prevention methods of HP caused by *Mycobacterium avium* should include protection, coagulation, flocculation, sedimentation, filtration, disinfection and protection of water distribution system.⁶⁷

Prognosis

HP evolution is highly variable and depends essentially on the time and concentration of antigen exposure. Individuals with the acute form of disease, but who had early detection and an immediate eviction of the causal antigen, tend to have an excellent prognosis. In chronic forms, a partial recovery may also occur; however, in some cases, the disease tends to progress, leading to a permanent loss of lung function, irreversible pulmonary

fibrosis and death, even after antigen eviction and appropriate treatment.^{6,90} For example, about 20% of the acute forms of FL evolve into chronic forms, hence into irreversibility²⁹ and fatal HP cases have been reported to be related to acute exacerbations after chronic exposure to some antigens, namely avian protein antigens, thermophilic actinomycetes, molds, heated plastics, among others.^{71,90,91}

Mortality data are scarce in the literature; however, in England and Wales, from 1968 to 2008, 878 HP deaths were reported,⁹² while in a study performed in Denmark, 5-years survival rate was 93%.⁷ In chronic HP, the average survival rate is of 7 years.¹

Factors associated with a poor prognosis include longer exposure period, high-intensity antigen exposure, advanced age, smoking, and a radiological and/or histological pattern with fibrosis.^{1,6,20,89,93} The antigen type may also influence the prognosis, as there is some data suggesting that BFL may have a worse prognosis than FL.⁵ However, Braun et al. (1979) suggest that exacerbations/relapses are the factors that most influence a detrimental evolution at long-term.⁹⁴ Further, Fernandez-Pérez et al. (2013) following up 142 HP cases reported that the non-identification of antigen was associated with a decrease in survival from 18.2 to 9.3 years.³⁸

Conclusion

HP occurs only in a small number of individuals exposed to causal antigens. Most individuals are only sensitized, since the development of the disease is based on the interaction between inducing factors (causal antigen) and promoters, itself related to the host (genetic background and additional environmental factors), leading to dysregulation of the immunity system and consequent persistent inflammation.

Several forms of the disease have been described, being the most common caused by the inhalation of bacteria, proteins, fungi, or mycobacteria present in the host environment,

such as workplace, home environment or recreational activities. Other substances, such as chemicals (namely, isocyanates or acrylates) may also act as triggering agents, despite less commonly associated with the disease.

The diagnosis of HP should be based on a proactive search for potential antigen sources, whose identification is often hampered by the unrecognition of some sources and/or by the lack of standardized detection methods of sensitization. In this context, it would be legitimate to create multidisciplinary Public Health teams to collect and to evaluate *in locus* potentially suspicious material.

Eviction of the causal agent exposure is the cornerstone of HP management, since antigen inhalation maintenance has prognostic implications, with the consequent progression and reduction of survival rate. In this way, protection measures should be implemented, in particular at the individual level or at the exposure source itself. A longer exposure period and of high antigenic intensity, the type of antigen and the non-identified exposure source are associated with a reserved prognosis.

Conflicts of interest

The authors declare no conflicts of interest.

(A)

(B)

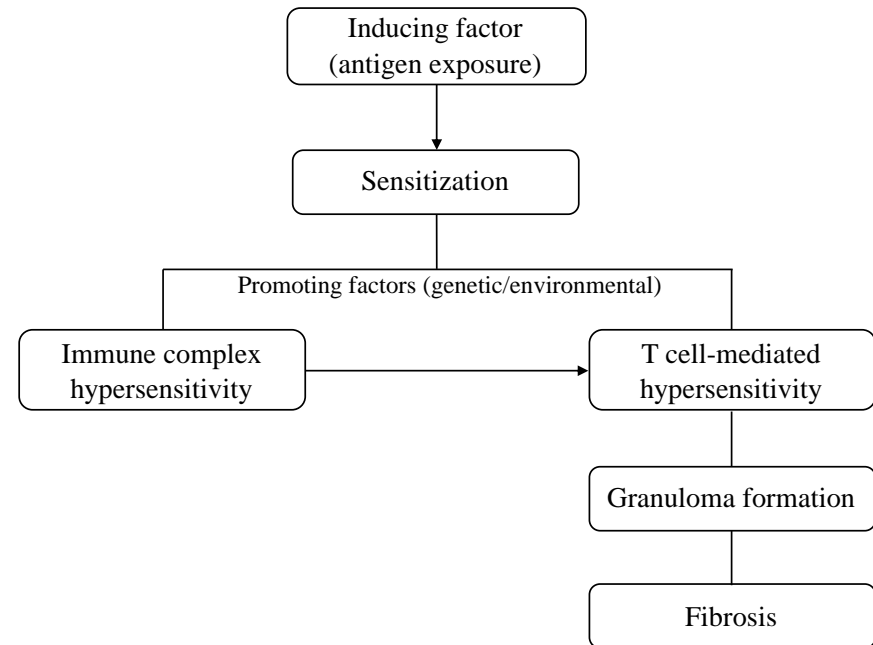

Figure 1. Pathogenesis of hypersensitivity pneumonitis (HP). (A) Classical immunopathological mechanisms proposed for HP (adapted from Delgado et al. ⁹⁵) (B) Persistent antigen exposure and sensitization associates with local antigen-antibody complex deposition, macrophage activation, mononuclear cell recruitment and predominant Th1 cell-mediated response; continuous exposure leads to critical changes in the lung, ending in fibrosis. ^{4,17}

Table 1. Clinical classification of hypersensitivity pneumonitis. ^{1,16}

	Acute/subacute HP	Chronic HP
Exposure to causal antigen	Intermittent high-level exposure (the subacute form develops more insidiously and it is caused by a more prolonged and less intense exposure to the agent compared with the acute form)	Continuous low-level exposure
Onset of symptoms	4-8 hours or days after exposure	Insidious, over weeks to months
Signs and symptoms	Cough, dyspnea, asthenia, malaise and fever	Cough, dyspnea, asthenia and weight loss
Physical examination	Bilateral widespread crackles; sometimes auscultation is normal	Inspiratory crackles, cyanosis, and <i>cor pulmonale</i>
Outcome	Symptoms decrease in a few hours or even days, after eviction of causative agent. Exacerbations may occur when the subject is again exposed to the allergen-containing environment	End-stage fibrotic disease and/or emphysema Exacerbations may occur despite avoidance of exposure

HP, hypersensitivity pneumonitis

Table 2. Causal antigens of hypersensitivity pneumonitis. ^{4,6,34,55,56}

Specific antigens	Sources	Type of disease
Bacteria		
<i>Acinetobacter</i> spp.	Contaminated water, contaminated machine fluid	Machine operator's lung
<i>Achromobacter</i>	Contaminated humidifiers	Humidifier lung
<i>Bacillus</i> spp.	Contaminated humidifier water, sawdust, moist	Woodworker's lung, humidifier lung
<i>Erwinia herbicola</i>	Moldy hay, grain	Farmer's lung
<i>Lichtheimia corymbifera</i>		
<i>Saccharopolyspora rectivirgula</i>		
<i>Streptomyces thermohygroscopicus</i>		
<i>Thermoactinomyces vulgaris</i>		
<i>Thermoactinomyces viridis</i>		
<i>Thermoactinomyces sacchari</i>		
<i>Streptomyces albus</i>	Contaminated compost, edible mushroom manure, hay dusty soil	Farmer's lung, mushroom grower's lung
<i>Thermoactinomyces sacchari</i>	Moldy sugarcane, hay, straw, moldy plants	Bagassosis, Farmer's lung
Fungi/yeasts		
<i>Absidia corymbifera</i>	Hay, straw, plant material, contaminated humidifiers	Farmer's lung, humidifier lung
<i>Alternaria alternata</i>	Contaminated humidifiers, wood pulp, dust	Humidifier lung, woodworker's lung
<i>Aspergillus</i> spp. (e.g. <i>A. fumigatus</i> , <i>A. niger</i>)	Contaminated barley, hay, straw, moldy plants, mushrooms, cheese. Contaminated houses, humidifiers, molds on the walls	Farmer's lung, Mushrooms worker's lung, Cheese workers' HP; Domestic HP, Humidifier lung
<i>Aspergillus oryzae</i>	<i>Aspergillus</i> enzyme in baking agents, soy	Fungal alveolitis, soya dust alveolitis
<i>Aureobasidium</i> spp.	Contaminated sauna water, domestic ventilation and cooling systems, steam iron water, potted flowers, greenhouse	Humidifiers lung, indoor fountain HP, sauna taker's lung, steam iron lung
<i>Botrytis cinerea</i>	Mold on grapes	Wine-grower's lung

<i>Candida albicans</i>	Saxophone	Sax lung
<i>Cephalosporium</i> spp.	Contaminated basement, contaminated humidifier, potted flowers, greenhouse	Humidifier lung, Japanese summer-type HP
<i>Chrysonilia sitophila</i>	Moldy cork	Suberosis
<i>Cryptococcus albidus</i> , <i>C. neoformans</i>	Contaminated houses	Summer type HP
<i>Cladosporium herbarum</i> , <i>C. cladosporioides</i>	Mold on ceiling	Mold alveolitis, indoor air HP, Hot-tub lung
<i>Eurotium amstelodami</i>	Contaminated humidifiers, hay	Humidifier lung, Farmer's lung
<i>Fusarium culmorum</i>	Ultrasound nebulizers	Indoor fountain HP
<i>Fusarium</i> spp.	Molds in living and working spaces, molds on plants	Indoor air alveolitis; humidifier lung
<i>Mucor</i> spp.	Moldy wood, contaminated humidifiers, sawdust	Woodworker's lung; cork worker's lung, humidifier
<i>Mucor stolonifer</i>	Moldy paprika pods	Paprika slicer's lung historical
<i>Penicillium casei</i>	Moldy cheese, white coating on salami, contaminated humidifiers	Cheese washer's lung, humidifiers lung, salami producer's lung
<i>Penicillium glabrum</i>	Moldy cork, white coating on salami, molds in apartments	Salami producer's lung, cork worker's lung (suberosis), summer-type HP
<i>Penicillium</i> spp.	Contaminated basement, moldy cork, molds on fruits and vegetables	Basement lung, onion worker's lung, potato worker's lung, fruit grower's lung, suberosis
<i>Saccharomyces cerevisiae</i>	Baker's yeasts, brewer's yeasts, wine yeasts	Farmer's lung, yeast powder alveolitis
<i>Trichosporon cutaneum</i>	Contaminated houses	Summer-type HP
<i>Trochoderma viridae</i>	Molds in ultrasound nebulizers, potted flowers, greenhouses, mold on wood, paper, citrus fruits	Indoor air alveolitis, humidifier lung
<i>Wallemia sebi</i>	Hay, straw, plant material	Farmer's lung
Mycobacteria		
<i>NTM</i> (<i>Mycobacterium immunogenum</i> , <i>M. avium complex</i> , <i>M. chelonae</i> , <i>M. fortuitum</i> , <i>M. abscessus</i>)	Contaminated machine fluids, cutting fluids, cutting oils, wind instruments, contaminated water, whirlpools	Hot tub lung, Whirlpool alveolitis, Machine operator's lung, wind instrument alveolitis

Animal proteins

Animal fur dust	Animal pelts	Furrier's lung
Avian droppings, serum and feathers	Parakeets, canaries, budgerigars, pigeons, parrots, chicken, turkeys, geese, ducks, wild birds, pheasants	Bird fancier's lung
Avian feathers	Feathers beds, pillows, duvets	Feather duvet lung
Fish meal	Animal feed	Fish meal alveolitis
Protozoans	Contaminated air conditioners	Humidifier lung
Plant proteins		
Grain flour (wheat, rye, oats, maize)	Flour dust	Flour dust alveolitis
Legumes (soy)	Legumes (soy)	Soya dust alveolitis
Paprika	Paprika dust	Paprika splitters lung
Chemicals		
Acid anhydrides	Polyurethane foams, spray paints, elastomers, glues, adhesives, mattress, car parts, shoes, elastic synthetic fibers	Acid anhydride alveolitis, isocyanate alveolitis
Isocyanates		
Chloroethylene	Degreasing agents, cleaning agents, extraction agents	Chemical alveolitis
Methyl methacrylate	Dental materials, lacquer, resin, glues	Methacrylate alveolitis
Triglycidyl isocyanate	Powder paints, polyester powder	Pinter's lung
Metals		
Beryllium	Batteries, computers neon	Berylliosis
Cobalt	Hard metal alloys	Hard metal lung disease
Zinc	Zinc fumes	Zinc fumes alveolitis
HP, hypersensitivity pneumonitis; NTM, nontuberculous mycobacteria.		

Table 3. Birds associated with bird fancier's lung. ³⁰

Order	Animals
<i>Anseriformes</i>	Ducks
	Geese
<i>Columbiformes</i>	Pigeons
<i>Galliformes</i>	Chickens
	Partridges
	Pheasants
	Turkeys
<i>Passeriformes</i>	Canaries
<i>Psittaciformes</i>	Budgerigars
	Cockatoos
	Parrots

Table 4. Some common antigen panels and mixtures available for specific IgG quantification to evaluate exposure/sensitization in suspected hypersensitivity pneumonitis. (adapted from Vasakova et al.)⁶

Microorganism-related antigens
<p>Indoor Molds mix 1: <i>Penicilium notatum</i>, <i>Cladosporium herbatum</i>, <i>Aspergillus fumigatus</i>, <i>Alternaria alternata</i></p> <p>Indoor Molds mix 2: <i>Penicilium chrysogenum</i>, <i>Cladosporium herbatum</i>, <i>Mucor racemosus</i>, <i>Alternaria alternata</i></p> <p>Aspergillus spp mix: <i>Aspergillus fumigatus</i>, <i>A. terreus</i>, <i>A. niger</i>, <i>A. flavus</i></p> <p>Farm microorganisms mix: <i>Micropolyspora faeni</i>, <i>Thermoactinomyces vulgaris</i></p> <p><i>Alternaria alternata</i></p> <p><i>Aspergillus fumigatus</i></p> <p><i>Cladosporium herbatum</i></p> <p><i>Penicillium glabrum</i> (frequentans)</p> <p><i>Micropolyspora faeni</i></p> <p><i>Thermoactinomyces vulgaris</i></p>
Bird-related antigens
<p>Poultry feathers mix: goose, hen, duck, turkey</p> <p>Cage bird feather mix: parrot, budgerigar, canary, alexander, finch</p> <p>Bird feathers mix: goose, hen, ducks, parrot</p> <p>Budgerigar antigens: feather, droppings, serum</p> <p>Pigeon antigens: feather, droppings, serum</p> <p>Parrot antigens: feather, droppings, sera</p> <p>Pigeon serum</p> <p>Pigeon feathers</p> <p>Canary feathers</p>
Chemical antigens/haptens
<p>Paint polyester chemicals mix: <i>Toluen diisocyanate</i>, <i>Difenylmetan diisocyanate</i>, <i>Hexametylen diisocyanate</i>, <i>Phthalic anhydride</i></p>

AGRADECIMENTOS

À Dr.^a Patrícia Caetano Mota pela sua orientação, pelo suporte contínuo, pela disponibilidade e pela paciência, pelo saber que transmitiu, pelas opiniões e críticas. Foi um gosto ter sido sua orientanda.

Ao Grupo de Doenças Pulmonares Difusas do Centro Hospitalar de São João, Porto, pelo acolhimento e estímulo para realizar a presente monografia e por toda a colaboração na sua coautoria.

Aos restantes coautores pela disponibilidade e partilha de conhecimento.

ANEXO

PULMONOLOGY - GUIDE FOR AUTHORS

Types of article

Articles on original research: The text must not exceed 2500 words, excluding references and tables, and be organized into introduction, methods, results, discussion and conclusions, with a maximum of 4 tables and/or figures. In the materials and methods there must be a complete and appropriate reference to the statistical methods used and the results should be quite sufficiently explicit.

Review articles: *Pulmonology* publishes primarily review articles which have been requested by the editors. However, unsolicited articles submitted will be considered, particularly systematic reviews (meta-analysis). The text must not exceed 5000 words, excluding references and tables, with a maximum of 5 tables and/or figures in total. The reviews must be organized systematically in introduction, methods, results and discussion.

Short publications: Preliminary results or new findings could lead to short publications. The text should not exceed 1000 words, excluding references and tables, and be organized into introduction, methods, results and discussion, with a maximum of 2 tables and/or figures in total and up to 10 references. The short publications should be submitted with formal abstracts in English, of not more than 250 words.

Commentaries: Commentaries, essays, critical analyses or declarations of a position in relation to topics of interest in the area of health, particular the politics of health and medical education will be considered. The text must not exceed 900 words, excluding

references and tables, and include a maximum of one table or figure. Commentaries do not require abstracts; they will normally be at the request of the editors.

Special articles: Where appropriate the editorial board may invite one or various authors to write an article on a subject of particular formative interest in achieving the priorities of the journal and where the subject matter is not being addressed by other areas of study (for example postgraduate study).

Clinical case studies (case reports): The text should not exceed 1200 words, excluding references and tables, with a maximum of 2 tables and/or figures in total. Clinical case studies should be submitted with formal abstracts in English, of not more than 120 words. Depending on their interest and originality the clinical case studies may include a commentary/discussion by one of the editors or by an invited reviewer (**Clinical case study with discussion**).

Letters to the editor: Two types of letter to the editor are considered, clinical notes and correspondence.

Clinical notes stand for a very objective reporting of results of clinical observation or original research for which a detailed development is not appropriate. The text should not exceed 800 words, excluding references and tables, and can include a maximum of two tables or figures and up to 7 references.

Correspondence refers to a succinct commentaries on articles published in the Portuguese Journal of Pulmonology, preferably within the previous 6 months. In this case, the text should not exceed 500 words, excluding references and tables, and can include a maximum of one table or figure and up to 5 references.

Letters to the editor should not include abstracts.

In manuscripts signed by more than 6 authors (3 authors in the case of letters to the editor), there has to be an explicit explanation for such an extensive authorship.

Manuscripts submitted to the *Pulmonology* must conform to the recommendations indicated here and must be accompanied by a covering letter. The Editorial Board will acknowledge receipt of manuscripts, supplying information as to the orientation category given to the relevant article. Whenever there are editorial recommendations to changes to the manuscripts sent, the authors should supply a new version with an explanation of changes made. Correspondence between the authors and the journal should be conducted electronically, by the Elsevier Editorial System (<http://ees.elsevier.com/pulmoe>).

Submission checklist

You can use this list to carry out a final check of your submission before you send it to the journal for review. Please check the relevant section in this Guide for Authors for more details.

Ensure that the following items are present:

One author has been designated as the corresponding author with contact details:

- E-mail address
- Full postal address

All necessary files have been uploaded:

Manuscript:

- Include keywords
- All figures (include relevant captions)
- All tables (including titles, description, footnotes)
- Ensure all figure and table citations in the text match the files provided
- Indicate clearly if color should be used for any figures in print

Graphical Abstracts / Highlights files (where applicable)

Supplemental files (where applicable)

Further considerations

- Manuscript has been 'spell checked' and 'grammar checked'
- All references mentioned in the Reference List are cited in the text, and vice versa
- Permission has been obtained for use of copyrighted material from other sources (including the Internet)
- Relevant declarations of interest have been made
- Journal policies detailed in this guide have been reviewed
- Referee suggestions and contact details provided, based on journal requirements

For further information, visit our Support Center.

BEFORE YOU BEGIN

Ethics in publishing

Please see our information pages on Ethics in publishing and Ethical guidelines for journal publication.

Human and animal rights

If the work involves the use of human subjects, the author should ensure that the work described has been carried out in accordance with The Code of Ethics of the World Medical Association (Declaration of Helsinki) for experiments involving humans; Uniform Requirements for manuscripts submitted to Biomedical journals. Authors should include a statement in the manuscript that informed consent was obtained for experimentation with human subjects. The privacy rights of human subjects must always be observed.

All animal experiments should comply with the ARRIVE guidelines and should be carried out in accordance with the U.K. Animals (Scientific Procedures) Act, 1986 and associated guidelines, EU Directive 2010/63/EU for animal experiments, or the National Institutes of Health guide for the care and use of Laboratory animals (NIH Publications No. 8023, revised 1978) and the authors should clearly indicate in the manuscript that such guidelines have been followed.

Declaration of interest

All authors must disclose any financial and personal relationships with other people or organizations that could inappropriately influence (bias) their work. Examples of potential conflicts of interest include employment, consultancies, stock ownership, honoraria, paid expert testimony, patent applications/registrations, and grants or other funding. If there are no conflicts of interest then please state this: 'Conflicts of interest: none'. More information.

Submission declaration and verification

Submission of an article implies that the work described has not been published previously (except in the form of an abstract or as part of a published lecture or academic thesis or as an electronic preprint, see 'Multiple, redundant or concurrent publication' section of our ethics policy for more information), that it is not under consideration for publication elsewhere, that its publication is approved by all authors and tacitly or explicitly by the responsible authorities where the work was carried out, and that, if accepted, it will not be published elsewhere in the same form, in English or in any other language, including electronically without the written consent of the copyright-holder. To

verify originality, your article may be checked by the originality detection service CrossCheck.

Authorship

All authors should have made substantial contributions to all of the following: (1) the Conception and design of the study, or acquisition of data, or analysis and interpretation of data, (2) drafting the article or revising it critically for important intellectual content, (3) final approval of the version to be submitted.

Changes to authorship

Authors are expected to consider carefully the list and order of authors **before** submitting their manuscript and provide the definitive list of authors at the time of the original submission. Any addition, deletion or rearrangement of author names in the authorship list should be made only **before** the manuscript has been accepted and only if approved by the journal Editor. To request such a change, the Editor must receive the following from the **corresponding author**: (a) the reason for the change in author list and (b) written confirmation (e-mail, letter) from all authors that they agree with the addition, removal or rearrangement. In the case of addition or removal of authors, this includes confirmation from the author being added or removed. Only in exceptional circumstances will the Editor consider the addition, deletion or rearrangement of authors **after** the manuscript has been accepted. While the Editor considers the request, publication of the manuscript will be suspended. If the manuscript has already been published in an online issue, any requests approved by the Editor will result in a corrigendum.

Clinical trial results

In line with the position of the International Committee of Medical Journal Editors, the journal will not consider results posted in the same clinical trials registry in which primary registration resides to be prior publication if the results posted are presented in the form of a brief structured (less than 500 words) abstract or table. However, divulging results in other circumstances (e.g., investors' meetings) is discouraged and may jeopardise consideration of the manuscript. Authors should fully disclose all posting in registries of results of the same or closely related work.

Reporting clinical trials

Randomized controlled trials should be presented according to the CONSORT guidelines. At manuscript submission, authors must provide the CONSORT checklist accompanied by a flow diagram that illustrates the progress of patients through the trial, including recruitment, enrollment, randomization, withdrawal and completion, and a detailed description of the randomization procedure. The CONSORT checklist and template flow diagram are available online.

Registration of clinical trials

Registration in a public trials registry is a condition for publication of clinical trials in this journal in accordance with International Committee of Medical Journal Editors recommendations. Trials must register at or before the onset of patient enrolment. The clinical trial registration number should be included at the end of the abstract of the article. A clinical trial is defined as any research study that prospectively assigns human participants or groups of humans to one or more health-related interventions to evaluate the effects of health outcomes. Health-related interventions include any intervention used to modify a biomedical or health-related outcome (for example drugs, surgical

procedures, devices, behavioural treatments, dietary interventions, and process-of-care changes). Health outcomes include any biomedical or health-related measures obtained in patients or participants, including pharmacokinetic measures and adverse events. Purely observational studies (those in which the assignment of the medical intervention is not at the discretion of the investigator) will not require registration.

Copyright

Upon acceptance of an article, authors will be asked to complete a 'Journal Publishing Agreement' (see more information on this). An e-mail will be sent to the corresponding author confirming receipt of the manuscript together with a 'Journal Publishing Agreement' form or a link to the online version of this agreement.

Author rights

As an author you (or your employer or institution) have certain rights to reuse your work. More information.

Elsevier supports responsible sharing

Find out how you can share your research published in Elsevier journals.

Role of the funding source

You are requested to identify who provided financial support for the conduct of the research and/or preparation of the article and to briefly describe the role of the sponsor(s), if any, in study design; in the collection, analysis and interpretation of data; in the writing of the report; and in the decision to submit the article for publication. If the funding source(s) had no such involvement then this should be stated.

If no funding has been provided for the research, please include the following sentence:
This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Funding body agreements and policies

Elsevier has established a number of agreements with funding bodies which allow authors to comply with their funder's open access policies. Some funding bodies will reimburse the author for the Open Access Publication Fee. Details of existing agreements are available online.

Open access

This is an open access journal: all articles will be immediately and permanently free for everyone to read and download. To provide open access, this journal has an open access fee (also known as an article publishing charge APC) which needs to be paid by the authors or on their behalf e.g. by their research funder or institution. Permitted third party (re)use is defined by the following Creative Commons user licenses:

Creative Commons Attribution-NonCommercial-NoDerivs (CC BY-NC-ND) For non-commercial purposes, lets others distribute and copy the article, and to include in a collective work (such as an anthology), as long as they credit the author(s) and provided they do not alter or modify the article.

No fee is payable by the author as publishing costs are covered by the society.

Elsevier Publishing Campus

The Elsevier Publishing Campus (www.publishingcampus.com) is an online platform offering free lectures, interactive training and professional advice to support you in publishing your research. The College of Skills training offers modules on how to prepare, write and structure your article and explains how editors will look at your paper when it is submitted for publication. Use these resources, and more, to ensure that your submission will be the best that you can make it.

Language (usage and editing services)

Please write your text in good English (American or British usage is accepted, but not a mixture of these). Authors who feel their English language manuscript may require editing to eliminate possible grammatical or spelling errors and to conform to correct scientific English may wish to use the English Language Editing service available from Elsevier's WebShop.

Informed consent and patient details

Studies on patients or volunteers require ethics committee approval and informed consent, which should be documented in the paper. Appropriate consents, permissions and releases must be obtained where an author wishes to include case details or other personal information or images of patients and any other individuals in an Elsevier publication. Written consents must be retained by the author and copies of the consents or evidence that such consents have been obtained must be provided to Elsevier on request. For more information, please review the Elsevier Policy on the Use of Images or Personal Information of Patients or other Individuals. Unless you have written permission from the patient (or, where applicable, the next of kin), the personal details of any patient included

in any part of the article and in any supplementary materials (including all illustrations and videos) must be removed before submission.

Submission

Our online submission system guides you stepwise through the process of entering your article details and uploading your files. The system converts your article files to a single PDF file used in the peer-review process. Editable files (e.g., Word, LaTeX) are required to typeset your article for final publication. All correspondence, including notification of the Editor's decision and requests for revision, is sent by e-mail.

Submit your article

Please submit your article via <http://ees.elsevier.com/pulmoe>

All manuscripts are evaluated by members of the editorial board of the journal and acceptance for publication of articles or original research, clinical reports or series of case studies which are accepted, are subject to a technical assessment by the editorial board.

In this evaluation process articles may be:

- a) Accepted without alteration
- b) Accepted after suggested modifications have been agreed by the authors
- c) Refused

Modifications and revisions – In the case of articles being accepted subject to modifications, changes must be made by the author within fifteen days (for “minor” modifications) or 2 months (for “major” modifications). The proof reading will be the responsibility of the Editorial Board unless the authors indicate otherwise. In the latter

case the changes must be made within the time limit set by the Editorial Board, to comply with.

PREPARATION

Double-blind review

This journal uses double-blind review, which means the identities of the authors are concealed from the reviewers, and vice versa. More information is available on our website. To facilitate this, please include the following separately:

Title page (with author details): This should include the title, authors' names and affiliations, and a complete address for the corresponding author including an e-mail address.

Blinded manuscript (no author details): The main body of the paper (including the references, figures, tables and any Acknowledgements) should not include any identifying information, such as the authors' names or affiliations.

Use of word processing software

It is important that the file be saved in the native format of the word processor used. The text should be in single-column format. Keep the layout of the text as simple as possible. Most formatting codes will be removed and replaced on processing the article. In particular, do not use the word processor's options to justify text or to hyphenate words. However, do use bold face, italics, subscripts, superscripts etc. When preparing tables, if you are using a table grid, use only one grid for each individual table and not a grid for each row. If no grid is used, use tabs, not spaces, to align columns. The electronic text should be prepared in a way very similar to that of conventional manuscripts (see also the Guide to Publishing with Elsevier). Note that source files of figures, tables and text

graphics will be required whether or not you embed your figures in the text. See also the section on Electronic artwork.

To avoid unnecessary errors you are strongly advised to use the 'spell-check' and 'grammarcheck' functions of your word processor.

Article structure

Subdivision - unnumbered sections

Divide your article into clearly defined sections. Each subsection is given a brief heading. Each heading should appear on its own separate line. Subsections should be used as much as possible when cross-referencing text: refer to the subsection by heading as opposed to simply 'the text'.

Introduction

State the objectives of the work and provide an adequate background, avoiding a detailed literature survey or a summary of the results.

Material and methods

Provide sufficient detail to allow the work to be reproduced. Methods already published should be indicated by a reference: only relevant modifications should be described.

Results

Results should be clear and concise.

Discussion

This should explore the significance of the results of the work, not repeat them. A combined Results and Discussion section is often appropriate. Avoid extensive citations and discussion of published literature.

Conclusions

The main conclusions of the study may be presented in a short Conclusions section, which may stand alone or form a subsection of a Discussion or Results and Discussion section.

Appendices

If there is more than one appendix, they should be identified as A, B, etc. Formulae and equations in appendices should be given separate numbering: Eq. (A.1), Eq. (A.2), etc.; in a subsequent appendix, Eq. (B.1) and so on. Similarly for tables and figures: Table A.1; Fig. A.1, etc.

Essential title page information

- **Title.** Concise and informative. Titles are often used in information-retrieval systems. Avoid abbreviations and formulae where possible.
- **Author names and affiliations.** Please clearly indicate the given name(s) and family name(s) of each author and check that all names are accurately spelled. Present the authors' affiliation addresses (where the actual work was done) below the names. Indicate all affiliations with a lower-case superscript letter immediately after the author's name and in front of the appropriate address. Provide the full postal address of each affiliation, including the country name and, if available, the e-mail address of each author.

- **Corresponding author.** Clearly indicate who will handle correspondence at all stages of refereeing and publication, also post-publication. **Ensure that the e-mail address is given and that contact details are kept up to date by the corresponding author.**
- **Present/permanent address.** If an author has moved since the work described in the article was done, or was visiting at the time, a 'Present address' (or 'Permanent address') may be indicated as a footnote to that author's name. The address at which the author actually did the work must be retained as the main, affiliation address. Superscript Arabic numerals are used for such footnotes.

Abstract

A concise and factual abstract is required. The abstract should state briefly the purpose of the research, the principal results and major conclusions. An abstract is often presented separately from the article, so it must be able to stand alone. For this reason, References should be avoided, but if essential, then cite the author(s) and year(s). Also, non-standard or uncommon abbreviations should be avoided, but if essential they must be defined at their first mention in the abstract itself.

Structured abstract

A structured abstract, by means of appropriate headings, should provide the context or background for the research and should state its purpose, basic procedures (selection of study subjects or laboratory animals, observational and analytical methods), main findings (giving specific effect sizes and their statistical significance, if possible), and principal conclusions. It should emphasize new and important aspects of the study or observations.

The headings will consist of: «Introduction and Objectives», «Patients or Materials and Methods», «Results» and «Conclusions».

Keywords

Immediately after the abstract, provide a maximum of 6 keywords, using British spelling and avoiding general and plural terms and multiple concepts (avoid, for example, 'and', 'of'). Be sparing with abbreviations: only abbreviations firmly established in the field may be eligible. These keywords will be used for indexing purposes.

Abbreviations

Define abbreviations that are not standard in this field in a footnote to be placed on the first page of the article. Such abbreviations that are unavoidable in the abstract must be defined at their first mention there, as well as in the footnote. Ensure consistency of abbreviations throughout the article.

Acknowledgements

Collate acknowledgements in a separate section at the end of the article before the references and do not, therefore, include them on the title page, as a footnote to the title or otherwise. List here those individuals who provided help during the research (e.g., providing language help, writing assistance or proof reading the article, etc.).

Formatting of funding sources

List funding sources in this standard way to facilitate compliance to funder's requirements:

Funding: This work was supported by the National Institutes of Health [grant numbers xxxx, yyyy]; the Bill & Melinda Gates Foundation, Seattle, WA [grant number zzzz]; and the United States Institutes of Peace [grant number aaaa].

It is not necessary to include detailed descriptions on the program or type of grants and awards. When funding is from a block grant or other resources available to a university, college, or other research institution, submit the name of the institute or organization that provided the funding.

If no funding has been provided for the research, please include the following sentence: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Units

Follow internationally accepted rules and conventions: use the international system of units (SI). If other units are mentioned, please give their equivalent in SI.

Math formulae

Please submit math equations as editable text and not as images. Present simple formulae in line with normal text where possible and use the solidus (/) instead of a horizontal line for small fractional terms, e.g., X/Y . In principle, variables are to be presented in italics. Powers of e are often more conveniently denoted by exp. Number consecutively any equations that have to be displayed separately from the text (if referred to explicitly in the text).

Embedded math equations

If you are submitting an article prepared with Microsoft Word containing embedded math equations then please read this related support information.

Artwork

Image manipulation

Whilst it is accepted that authors sometimes need to manipulate images for clarity, manipulation for purposes of deception or fraud will be seen as scientific ethical abuse and will be dealt with accordingly. For graphical images, this journal is applying the following policy: no specific feature within an image may be enhanced, obscured, moved, removed, or introduced. Adjustments of brightness, contrast, or color balance are acceptable if and as long as they do not obscure or eliminate any information present in the original. Nonlinear adjustments (e.g. changes to gamma settings) must be disclosed in the figure legend.

Electronic artwork

General points

- Make sure you use uniform lettering and sizing of your original artwork.
- Embed the used fonts if the application provides that option.
- Aim to use the following fonts in your illustrations: Arial, Courier, Times New Roman, Symbol, or use fonts that look similar.
- Number the illustrations according to their sequence in the text.
- Use a logical naming convention for your artwork files.
- Provide captions to illustrations separately.
- Size the illustrations close to the desired dimensions of the published version.
- Submit each illustration as a separate file.

A detailed guide on electronic artwork is available.

You are urged to visit this site; some excerpts from the detailed information are given here.

Formats

If your electronic artwork is created in a Microsoft Office application (Word, PowerPoint, Excel) then please supply 'as is' in the native document format.

Regardless of the application used other than Microsoft Office, when your electronic artwork is finalized, please 'Save as' or convert the images to one of the following formats (note the resolution requirements for line drawings, halftones, and line/halftone combinations given below):

EPS (or PDF): Vector drawings, embed all used fonts.

TIFF (or JPEG): Color or grayscale photographs (halftones), keep to a minimum of 300 dpi.

TIFF (or JPEG): Bitmapped (pure black & white pixels) line drawings, keep to a minimum of 1000 dpi.

TIFF (or JPEG): Combinations bitmapped line/half-tone (color or grayscale), keep to a minimum of 500 dpi.

Please do not:

- Supply files that are optimized for screen use (e.g., GIF, BMP, PICT, WPG); these typically have a low number of pixels and limited set of colors;
- Supply files that are too low in resolution;
- Submit graphics that are disproportionately large for the content.

Color artwork

Please make sure that artwork files are in an acceptable format (TIFF (or JPEG), EPS (or PDF) or MS Office files) and with the correct resolution. If, together with your accepted article, you submit usable color figures then Elsevier will ensure, at no additional charge, that these figures will appear in color online (e.g., ScienceDirect and other sites). Further information on the preparation of electronic artwork.

Illustration services

Elsevier's WebShop offers Illustration Services to authors preparing to submit a manuscript but concerned about the quality of the images accompanying their article. Elsevier's expert illustrators can produce scientific, technical and medical-style images, as well as a full range of charts, tables and graphs. Image 'polishing' is also available, where our illustrators take your image(s) and improve them to a professional standard. Please visit the website to find out more.

Figure captions

Ensure that each illustration has a caption. Supply captions separately, not attached to the figure. A caption should comprise a brief title (**not** on the figure itself) and a description of the illustration. Keep text in the illustrations themselves to a minimum but explain all symbols and abbreviations used.

Tables

Please submit tables as editable text and not as images. Tables can be placed either next to the relevant text in the article, or on separate page(s) at the end. Number tables consecutively in accordance with their appearance in the text and place any table notes below the table body.

Be sparing in the use of tables and ensure that the data presented in them do not duplicate results described elsewhere in the article. Please avoid using vertical rules and shading in table cells.

References

Citation in text

Please ensure that every reference cited in the text is also present in the reference list (and vice versa). Any references cited in the abstract must be given in full. Unpublished results and personal communications are not recommended in the reference list, but may be mentioned in the text. If these references are included in the reference list they should follow the standard reference style of the journal and should include a substitution of the publication date with either 'Unpublished results' or 'Personal communication'. Citation of a reference as 'in press' implies that the item has been accepted for publication.

Reference links

Increased discoverability of research and high quality peer review are ensured by online links to the sources cited. In order to allow us to create links to abstracting and indexing services, such as Scopus, CrossRef and PubMed, please ensure that data provided in the references are correct. Please note that incorrect surnames, journal/book titles, publication year and pagination may prevent link creation. When copying references, please be careful as they may already contain errors. Use of the DOI is encouraged.

A DOI can be used to cite and link to electronic articles where an article is in-press and full citation details are not yet known, but the article is available online. A DOI is guaranteed never to change, so you can use it as a permanent link to any electronic article. An example of a citation using DOI for an article not yet in an issue is: VanDecar J.C.,

Russo R.M., James D.E., Ambeh W.B., Franke M. (2003). Aseismic continuation of the Lesser Antilles slab beneath northeastern Venezuela. *Journal of Geophysical Research*, <http://dx.doi.org/10.1029/2001JB000884>. Please note the format of such citations should be in the same style as all other references in the paper.

Web references

As a minimum, the full URL should be given and the date when the reference was last accessed. Any further information, if known (DOI, author names, dates, reference to a source publication, etc.), should also be given. Web references can be listed separately (e.g., after the reference list) under a different heading if desired, or can be included in the reference list.

Data references

This journal encourages you to cite underlying or relevant datasets in your manuscript by citing them in your text and including a data reference in your Reference List. Data references should include the following elements: author name(s), dataset title, data repository, version (where available), year, and global persistent identifier. Add [dataset] immediately before the reference so we can properly identify it as a data reference. This identifier will not appear in your published article.

References in a special issue

Please ensure that the words 'this issue' are added to any references in the list (and any citations in the text) to other articles in the same Special Issue.

Reference style

Text: Indicate references by superscript numbers in the text. The actual authors can be referred to, but the reference number(s) must always be given.

List: Number the references in the list in the order in which they appear in the text.

Examples:

Reference to a journal publication:

1. Van der Geer J, Hanraads JAJ, Lupton RA. The art of writing a scientific article. *J Sci Commun* 2010;**163**:51–9.

Reference to a book:

2. Strunk Jr W, White EB. *The elements of style*. 4th ed. New York: Longman; 2000.

Reference to a chapter in an edited book:

3. Mettam GR, Adams LB. How to prepare an electronic version of your article. In: Jones BS, Smith RZ, editors. *Introduction to the electronic age*, New York: E-Publishing Inc; 2009, p. 281–304.

Reference to a website:

4 . Cancer Research UK. Cancer statistics reports for the UK, <http://www.cancerresearchuk.org/aboutcancer/statistics/cancerstatsreport/>; 2003 [accessed 13 March 2003].

Reference to a dataset:

[dataset] 5. Oguro M, Imahiro S, Saito S, Nakashizuka T. Mortality data for Japanese oak wilt disease and surrounding forest compositions, Mendeley Data, v1; 2015. <https://doi.org/10.17632/xwj98nb39r.1>.

Note shortened form for last page number. e.g., 51–9, and that for more than 6 authors the first 6 should be listed followed by 'et al.' For further details you are referred to 'Uniform Requirements for Manuscripts submitted to Biomedical Journals' (*J Am Med Assoc* 1997;**277**:927–34)(see also Samples of Formatted References).

Journal abbreviations source

Journal names should be abbreviated according to the List of Title Word Abbreviations.

Video

Elsevier accepts video material and animation sequences to support and enhance your scientific research. Authors who have video or animation files that they wish to submit with their article are strongly encouraged to include links to these within the body of the article. This can be done in the same way as a figure or table by referring to the video or animation content and noting in the body text where it should be placed. All submitted files should be properly labeled so that they directly relate to the video file's content. In order to ensure that your video or animation material is directly usable, please provide the files in one of our recommended file formats with a preferred maximum size of 150 MB. Video and animation files supplied will be published online in the electronic version of your article in Elsevier Web products, including ScienceDirect. Please supply 'stills' with your files: you can choose any frame from the video or animation or make a separate image. These will be used instead of standard icons and will personalize the link to your video data. For more detailed instructions please visit our video instruction pages. Note: since video and animation cannot be embedded in the print version of the journal, please provide text for both the electronic and the print version for the portions of the article that refer to this content.

Supplementary material

Supplementary material such as applications, images and sound clips, can be published with your article to enhance it. Submitted supplementary items are published exactly as they are received (Excel or PowerPoint files will appear as such online). Please submit

your material together with the article and supply a concise, descriptive caption for each supplementary file. If you wish to make changes to supplementary material during any stage of the process, please make sure to provide an updated file. Do not annotate any corrections on a previous version. Please switch off the 'Track Changes' option in Microsoft Office files as these will appear in the published version.

AFTER ACCEPTANCE

Proofs

One set of page proofs (as PDF files) will be sent by e-mail to the corresponding author (if we do not have an e-mail address then paper proofs will be sent by post) or, a link will be provided in the e-mail so that authors can download the files themselves. Elsevier now provides authors with PDF proofs which can be annotated; for this you will need to download the free Adobe Reader, version 9 (or higher). Instructions on how to annotate PDF files will accompany the proofs (also given online). The exact system requirements are given at the Adobe site. If you do not wish to use the PDF annotations function, you may list the corrections (including replies to the Query Form) and return them to Elsevier in an e-mail. Please list your corrections quoting line number. If, for any reason, this is not possible, then mark the corrections and any other comments (including replies to the Query Form) on a printout of your proof and scan the pages and return via e-mail. Please use this proof only for checking the typesetting, editing, completeness and correctness of the text, tables and figures. Significant changes to the article as accepted for publication will only be considered at this stage with permission from the Editor. We will do everything possible to get your article published quickly and accurately. It is important to ensure that all corrections are sent back to us in one communication: please check

carefully before replying, as inclusion of any subsequent corrections cannot be guaranteed. Proofreading is solely your responsibility.

Offprints

The corresponding author will be notified and receive a link to the published version of the open access article on ScienceDirect. This link is in the form of an article DOI link which can be shared via email and social networks. For an extra charge, paper offprints can be ordered via the offprint order form which is sent once the article is accepted for publication. Both corresponding and co-authors may order offprints at any time via Elsevier's Webshop. Authors requiring printed copies of multiple articles may use Elsevier Webshop's 'Create Your Own Book' service to collate multiple articles within a single cover.

AUTHOR INQUIRIES

Visit the Elsevier Support Center to find the answers you need. Here you will find everything from Frequently Asked Questions to ways to get in touch.

You can also check the status of your submitted article or find out when your accepted article will be published.
